QUESTION ::

Write a Java program to implement a **Bank Account Management System**.

Create a class named **BankAccount** with the following data members: accountNumber, accountHolderName and balance.

Create a **parameterized constructor** to initialize all the account details.

Implement the following methods:

- **deposit(double amount)** - Adds the given amount to the balance.
- **withdraw(double amount)** - Withdraws money only if sufficient balance is available.
- **checkBalance()** - Returns the current balance.
- **displayAccount()** - Displays account details and balance.

In the **main()** method, read the account details and initial balance. Create an object using the parameterized constructor. Perform one deposit and one withdrawal operation and display the final account details.

Use separate methods for each operation. Do not perform all the calculations directly inside the main() method.

CODE :: public class BankAccount {

String accountNumber, accountHolderName;

double balance;

BankAccount(String n, String h, double b) {

accountNumber = n;

accountHolderName = h;

balance = b;

}

void deposit(double a) {

balance += a;

}

void withdraw(double a) {

if (a <= balance)

balance -= a;

}

double checkBalance() {

```
return balance;
}
void displayAccount() {
System.out.println("Account Number: " + accountNumber);
System.out.println("Account Holder: " + accountHolderName);
System.out.println("Balance: " + balance);
}
public static void main(String[] args) {
BankAccount a = new BankAccount("12345", "Ishika", 10000);
a.deposit(2000);
a.withdraw(3000);
a.displayAccount();
}
}
```
